

Diabetes

Model card with explicit reference parameters

This card records the model using an explicit reference parameter set. The purpose is to stop the model card from depending on hidden defaults inside the model JSON.

Identity

Model	Diabetes
Reference parameter set	reference-parameter-set:ncd-diabetes:synthetic-v1
Scenario registry	scenario-registry:ncd-diabetes:reference-synthetic-v1
Source model hash	cccc445e13b4da72

Provenance

The current parameter snapshot copies 459 generated values from the source model. It includes 47 external data-backed values and 388 static single-value assumptions. 43 country-bound parameters are made explicit in the synthetic reference set.

Internal validity

The current-reference test materialises the model from the snapshot and runs it for Ethiopia. The synthetic-reference test materialises the model with the synthetic reference country where possible. These tests are execution checks, not external scientific validation.

Current-reference run	pass
Current-reference rows	30837
Synthetic-reference run	pass
Synthetic-reference rows	30837

Face validity

The headline table below uses the synthetic reference fixture run. This is a plausibility prompt for the explicit-reference machinery, not a claim that the synthetic reference parameters are externally validated.

Headline outputs

Measure	2025	2030	2040
Population at risk	955,479	950,333	935,325
Diabetes prevalence state	30,760	34,467	41,237
Diabetes incidence flow	956	951	937
Diabetes mortality flow	15	17	20
Healthy years lived	995,249	994,378	988,192

Limits

This is the first conservative migration. It preserves non-country embedded parameters and makes the reference-set machinery explicit. The next stronger version should replace disease, risk-factor, and cost inputs with declared synthetic fixture values where those are intended to be stable across evidence updates.
